Vuvuzelas: *Ex Africa semper aliquid novis* – again?

**To the Editor:** The vuvuzela, or *le pata* (Tswana), or ‘stadium horn,’ has recently become an object of intense interest because of its prominence during the FIFA World Cup in South Africa. Its history has been well documented.¹ We all now know what a vuvuzela is. Its monotonous sound, if produced simultaneously by, say, 40,000 soccer enthusiasts, can fill an entire stadium for hours on end, to the intense irritation of players, coaches, non-participating spectators, TV audiences, and many more (for miles around the stadium).

The impact of the vuvuzela on the human ear has recently been studied, and the recreational risk that vuvuzelas pose to spectators in a stadium is significant.² It may also disseminate droplet-spread infections and be used as a weapon by soccer hooligans; among other things, it has been described as ‘an instrument from hell’ ¹.

Despite these negatives, Mr Sepp Blatter felt that ‘We should not try to Europeanize an African World Cup ... that is what African and South African football is all about – noise, excitement, dancing, shouting and enjoyment.’³ Therefore, as a voice of moderation in the assessment of toxic granulation must be based on experienced technologists, unfortunately not generally available for the training of the examiners.

I am of the considered opinion that the vuvuzela must have played a role in pacifying the crowds – possibly by keeping its users occupied. It kept their hands, mouths, lungs and minds busy while at the same time producing noise. There was apparent competition between users to see who could make the most noise. People of all ages, sexes and colours blew the vuvuzela. It even found its way into the anthem. South Africa scored very high points in the international TV audiences, and many more (for miles around the stadium).

The vuvuzela, if indeed some potentially ‘bad’ energy, however or even crime. It seemed to have some binding effect on fans from various countries. If indeed some potentially ‘bad’ energy, however little, was dissipated in this way, and if indeed it possibly had some unifying, positive, syncretic effect between peoples of different ethnic groups and nationalities, then I would be quite happy to continue living with the vuvuzela, even if it means some degree of hearing loss and living with some noise pollution. After all, Africa is a loud, bright, noisy and sometimes infernal continent.

In South Africa, we have just produced a new antiviral vaginal gel, which seems to be effective; we have produced yet another golf champion; and we have put the vuvuzela in the limelight. Possibly the vuvuzela is not all bad news. As the old Romans said: *Ex Africa semper aliquid novis*. (There is always something new out of Africa.)

**CRP and toxic granulation**

**To the Editor:** I read the article on CRP and toxic granulation with great interest.¹ The authors concluded: ‘The proposed system can be applied to patients with inflammatory or infectious conditions, where grading of toxic granulation of neutrophils can possibly be used as a surrogate marker to assess infection or inflammation and their response to treatment.’¹ I agree that the new system can be useful in clinical practice. However, there are some points of concern. Firstly, the assessment of toxic granulation must be based on experienced clinical microscopy;² this might not be available in rural hospitals. Secondly, there are many confounding factors that can affect the CRP level, and this aspect was not totally controlled in the article.³

**Dr Van de Vyver replies:** Laboratory confirmation of the presence of inflammation can be problematic in certain settings. This is a particular issue in settings where anti-inflammatory drugs – especially corticosteroids – are administered. In this setting, a combination of assays is usually employed to provide a cumulative impression of the presence or absence of infection or inflammation. C-reactive protein (CRP) is a widely utilised assay in the evaluation of inflammation. As with most immune assays, various factors can theoretically interfere with the final value reported. However, this seems to be a significant problem with highly sensitive assays (measuring levels below 10 mg/l)² as opposed to assays measuring levels in excess of 10 mg/l.²

We agree that assessment of toxic granulated neutrophils requires an experienced technologist, unfortunately not generally available in rural areas. The system is also potentially labour-intensive, with reproducibility highly dependent on the training of the examiners.

Toxic granulation can only serve as an additional tool to assess the presence of infection if there is diagnostic uncertainty. As a single parameter, it is of limited diagnostic value and can serve purely as a contribution to other infective markers.
