resuscitation before registering as general practitioners; hands-on courses on mannequins done at frequent intervals are also recommended. The National Committee on Confidential Enquiries into Maternal Deaths is promoting essential steps in the management of obstetric emergencies (ESMOE). This involves trainers visiting all health districts and carrying out training on mannequins and other visual aids on the emergency management of common conditions causing maternal deaths.

Previous SMRs have not identified cases of acute fatty liver of pregnancy (AFLP), but there is an impression that this condition does occasionally occur.12 Whether these deaths should be grouped under HDP is debatable. AFLP is defined as a condition that occurs abruptly in the second half of pregnancy and presents with increasing jaundice and right upper quadrant pain. The liver enzymes (transaminases) are abnormal and patients go on to develop coagulopathy and encephalopathy. Treatment involves supportive measures and delivery of the fetus. On pathological examination the liver shows fatty changes in the hepatocytes.12

There were 3 cases of maternal death grouped under AFLP. All took place at the same tertiary hospital and its geographical drainage area, all the patients were relatively young (26 - 30 years), parity 2 and in the second half of pregnancy, and all presented with jaundice and abdominal pain. One had mild hypertension, 2 had autopsies in keeping with fatty changes in the liver, and the third was said to have had all the clinical features of AFLP. As they were all from the same geographical area, the questions of viral infections, drug-related effects, or heavy alcohol intake are raised.

Conclusion

The majority of maternal deaths from hypertensive disorders in South Africa are associated with avoidable factors and substandard care. The challenge is to implement the recommendations arising from the SMRs. There is evidence from the 2005 - 2005 report that maternal deaths due to hypertension are decreasing, but more effort needs to be put into increasing the skills of health care professionals and improving the information on maternity care that we provide to women, fathers, families and communities.

Cytomegalovirus duodenitis, pseudotumour and cholangiopathy in advanced HIV

Bradley Yudelowitz, Adam Mahomed

Gastro-intestinal cytomegalovirus (CMV) infection manifests as oesophagitis, gastritis, enteritis and colitis.12 Reports of duodenal involvement are rare.12 We found only one reported CMV-induced pseudotumour of the duodenum and 14 CMV-induced gastro-intestinal pseudotumours.14

Case report

A 35-year-old woman presented with cholestatic jaundice and partial bowel obstruction following 3 months’ history of intermittent abdominal pain, nausea and vomiting. She had been diagnosed HIV positive 2 years before presentation, and had had no further follow-up. An abdominal ultrasound scan demonstrated splenic micro-abscesses, mesenteric and para-aortic lymphadenopathy and an indiscernible mass in the region of the head of the pancreas. A computed tomography (CT) scan (Fig. 1) confirmed a mass inseparable from the first part of the duodenum (D1) in the region of the head of the pancreas, compressing the common bile duct (CBD). Magnetic resonance cholangiopancreatography (MRCP) (Fig. 2) demonstrated dilated intrahepatic ducts and a long distal CBD stricture. Empiric tuberculosis (TB) treatment was started in view of the intra-abdominal lymph nodes, splenic micro-abscesses and pancreatic mass, with poor clinical response.

Because of the patient’s poor clinical response to TB treatment gastroscopy was performed, and an exophytic lesion at the second part of the duodenum (D2) was encountered which the scope was

 Bradley Yudelowitz was a medical officer at the Reproductive Health and HIV Research Unit, University of the Witwatersrand, Johannesburg, at the time of writing. Adam Mahomed is clinical head of the Division of Medical Gastroenterology, Department of Internal Medicine, Charlotte Maxeke Johannesburg Academic Hospital and University of the Witwatersrand.

The patient improved slowly over the next few months. She continued taking antiretrovirals with minimal complications, and completed 9 months of TB treatment. At the time of writing she continued taking antiretrovirals with minimal complications, and a CD4 count of 53 cells/µl.

She reported a return of libido and was practising safe sex with a discordant partner. A repeat endoscopy one year after her initial presentation demonstrated a normal duodenum with unremarkable histology. Liver function improved significantly and was stable at the time of writing.

Discussion

CMV is an important pathogen, causing a wide spectrum of disease from asymptomatic infection to mononucleosis syndrome in immunocompetent individuals to disseminated disease in immunocompromised individuals.

Once acquired by symptomatic or asymptomatic primary infection, CMV persists indefinitely in various cell types and organs including salivary glands, lung, liver, kidney, bowel, pancreas, adrenal glands and central nervous system. The cellular inflammatory response consists of plasma cells, lymphocytes and monocyte-macrophages. Granulomatous reactions occasionally develop, usually in the liver. Infection will usually remain latent. Reactivation syndromes frequently develop when T-lymphocyte-mediated immunity is compromised.

Active significant CMV infection is sometimes difficult to diagnose definitively in patients with advanced HIV disease because of its propensity to infect rapidly dividing cells and the frequent presence of other opportunistic infections. Fatal CMV infection is often associated with persistent viraemia and the involvement of multiple organ systems, often in conjunction with another opportunistic infection such as TB. The guidelines for ganciclovir use remain anecdotal.

CMV is often noted in pathological specimens and should not be viewed as incidental, even in the presence of another infection. CMV pseudotumour should be considered as a differential diagnosis in mass lesions of the gastrointestinal tract in the immunocompromised patient. The tumour does respond to antiviral treatment.

The exact incidence and cause of HIV cholangiopathy has yet to be determined, but infection-related damage to the biliary tree has been suggested and CMV infection appears to be one possible cause.

This is the first reported case of CMV-related duodenitis, pseudotumour and cholangiopathy of which we are aware. CMV is emerging as an important pathogen in patients with advanced HIV and other immunocompromised hosts. We propose that CMV infection associated with a concurrent infection is clinically significant in such patients. It should not be overlooked even in the presence of other opportunistic infection, and further research is required into how best to treat CMV and HIV co-infection.

Approval was obtained from the Ethics Committee of the University of the Witwatersrand. There were no conflicts of interest. Written consent was obtained from the patient.
