Cell phones offer many potential learning opportunities for healthcare workers – in particular, midwives, who are vitally important in the management of pregnant women and their newborn infants. The use of cell phones to improve access to continuing education for midwives may help to address the need for ongoing training, especially in rural primary care facilities, that cannot be met by expensive, traditional methods of centralised, tutor-based training. This application could contribute to better care for all pregnant women, and therefore assist in lowering the unacceptably high mortality rate of mothers and their infants in South Africa.

Few publications exist for controlled trials of the use of text messaging to improve healthcare in under-resourced settings. In Kenya, personal text messages to healthcare workers over a period of six months were well received by the midwives; the information was widely shared with colleagues and was believed to improve learning and patient care. Lack of access to the Internet, or failure to utilise this facility to obtain additional information, indicated that limitations still exist in internet-based distance education, especially in the public sector. The use of text messaging promises to provide cost-effective learning opportunities, and improve a wide range of clinical services, such as the management of HIV-infected children and adults.

6 months significantly improved the management of children with malaria.6

A recent project has brought essential healthcare lessons from the Perinatal Education Programme (PEP) to thousands of midwives through the medium of short message service (SMS) text messaging, using basic cell phones. The project aimed to assess whether this method of education is acceptable to midwives in the South African public and private sectors.

The PEP has been in force for 20 years to enable groups of newborn care. We hope to determine whether weekly text messages could improve the standard of knowledge and practice of nurses in primary care facilities. The use of cell phone text messaging promises to be widely shared with colleagues and was believed to improve learning and patient care. The messages often formed the basis of discussions and student teaching. The lack of access to the Internet, and failure to use this facility to obtain additional information, indicated that Internet-based distance education still has limitations, especially in the public sector.

A similar project is planned to provide essential messages on newborn care. We hope to determine whether weekly text messages could improve the standard of knowledge and practice of nurses in primary care facilities. The use of cell phone text messaging promises to provide cost-effective learning opportunities, and improve a wide range of clinical services, such as the management of HIV-infected children and adults.

<th>N</th>
</tr>
</thead>
<tbody>
<tr>
<td>Did you enjoy and learn from the weekly text messages? (Yes/Sometimes/No)</td>
<td>43 7 0</td>
</tr>
<tr>
<td>Did the information improve your clinical practice? (Yes/Perhaps/No)</td>
<td>36 12 2</td>
</tr>
<tr>
<td>Did you share and discuss the information with your colleagues? (Most times/Sometimes/No)</td>
<td>34 9 7</td>
</tr>
<tr>
<td>Did you ever contact the Sister Lilian website? (Yes/I wanted to but had no access/I could have but did not)</td>
<td>17 16 17</td>
</tr>
<tr>
<td>Do you think that PEP books would help you in your practice? (Yes/Perhaps but I have not seen the books/No)</td>
<td>49 1 0</td>
</tr>
<tr>
<td>Have you or will you buy PEP books after the text messages? (Yes/Maybe/No)</td>
<td>42 8 0</td>
</tr>
<tr>
<td>Would you like further text messages on other important topics? (Yes/ Perhaps/No)</td>
<td>50 0 0</td>
</tr>
</tbody>
</table>

At the end of the project, 50 recipients were randomly identified: 25 in the public and private sectors, respectively. These midwives were contacted by an independent consultant, and asked to answer 7 short questions; each question had 3 possible answers ranging from positive to negative (Table I). Additional comments were recorded.

**Results**

All 50 recipients were willing to participate in the survey: 86% enjoyed and learned from the weekly text messages, 72% believed that the messages improved their clinical practice, and 68% regularly shared and discussed the messages with their colleagues. A total of 68% had access to the Internet (56% in the public and 80% in the private sector), but only half used the facility. Most (98%) thought that the PEP books would help in their clinical practice, and 84% had already purchased the books or intended to do so. All respondents wanted to receive further text messages on other important topics.

Respondents' comments included: 'I loved the messages and learned a lot; the SMSs were a good reminder of things I already knew', 'I wrote the messages down so I could go back to them', 'I shared the messages with my students', 'I liked that they were short and quick to read', and 'Love the PEP books and use them.' Some found that the messages were too simple and wanted more detailed information; consequently, links to the publisher's website were included in each message. Many looked forward to the weekly messages and asked to be included in future text message projects, as they wanted more information on a wide range of perinatal topics.

**Conclusions**

This survey demonstrated that text messages via personal cell phones were well received by South African midwives; the information was widely shared with colleagues and was believed to improve learning and patient care. The messages often formed the basis of discussions and student teaching. The lack of access to the Internet, and failure to use this facility to obtain additional information, indicated that Internet-based distance education still has limitations, especially in the public sector.

A similar project is planned to provide essential messages on newborn care. We hope to determine whether weekly text messages could improve the standard of knowledge and practice of nurses in primary care facilities. The use of cell phone text messaging promises to provide cost-effective learning opportunities, and improve a wide range of clinical services, such as the management of HIV-infected children and adults.
